

Designing a POS Mapping experience

How I streamlined POS-to-Inventory mapping to reduce data errors by X%

Year	Timeline	Platform
2023 - 2024	3 months	Desktop web

- I led and execute end to end design process from ideation to production with collaboration with the team
- Adeline Kusuma
Product Designer
- William Arya
Supervisor
- Keith Tan
Head of Product
- Nagarjuna
Engineer Manager

My role is working on the design as well as being the co product manager together to propose the concept to my supervisor and with approval to the Head of the Product.

(Animated in GIF Mapping regular item)

I designed a split-view to help users instantly see the connection between POS items and inventory lists and real time validations.

II. Understanding

Problem
The old mapping process is difficult for user to use the mapping process and the impact is not obvious.

Users are our internal onboarding team. They hardly know whether the mapping result is correct to reduce the inventory or not.

Objectives
POS - Inventory mapping process to be easy to understand for user how the menu are linked to one another.

With this, the end goals would be when

- Increase speed of onboarding new customers
- Correctness data being deducted
- Improve status of after mapping

POS & F&B Inventory Management Flow

The primary challenge presented by this project comes from the fact that the menu hierarchy built within the Abacus POS system is outside the control of the Inventory Management team.

I also have limited context of imagining the usage as I am designing for the product that I have never used.

III. Design "Layout as a Solution"

To address this constraint, the design focus was placed on creating a user experience that guides customers through the mapping process

Dividing the layout into two distinct sections improves comprehension

The before

The after

Choose menu item on left side. Select item to map on right side, search key word will match based on the name on left side automatically and relevant result will start to appear

Providing total food cost helps to check if the item selected is the correct one to map by reviewing the item's cost.

We define the default food cost margin as a tool to help validate between the Menu Retail Price with the Total Food Cost.

This brings ease for user, in this case is the staff to ensure the item's mapped is correct.

Library

When designing complicated flow like this, it will be disorganized if I dont utilize a library of components

IV. Impact

1. Minimized Error Rates: By implementing real-time validation, users can now confirm the accuracy of every product mapping before finalizing.
2. Reduced Cognitive Load: The two-panel layout simplifies the visual relationship between menu items and complex recipe data.
3. Full System Coverage: Successfully bridged the gap between Abacus POS structures and internal inventory requirements.
4. Versatile Mapping: The system effectively handles both Main Products and Product Variants, ensuring no data is left unmanaged.

Impact

1. Minimized Error Rates: By implementing real-time validation, users can now confirm the accuracy of every product mapping before finalizing.
2. Reduced Cognitive Load: The two-panel layout simplifies the visual relationship between menu items and complex recipe data.
3. Bridges gaps in reporting

Takeaway

Designing for complex inventory systems taught me that clarity is the ultimate feature. By structuring the interface to mirror the user's mental model, we transformed a technical hurdle into a seamless workflow.
